Aspects of kinetic analysis are reviewed taking into account different scopes of applied heterogeneous catalysis: the micro-kinetic analysis for reaction synthesis, i.e. analysis of rate determining steps and derivation of optimised catalyst design; the kinetic analysis of complex reactions under closed-to-process conditions for optimisation of catalysts and reactor operation; the analysis of the interplay of kinetics and transport processes for optimisation reactor design as well as ...

It should be also mentioned that heterogeneous catalysts can undergo transformations during catalytic reactions (changes in morphology, phase transformations, sintering, etc.). Such changes are yet to be considered in kinetic analysis, even if there are already some examples when for example sintering is quantitatively described [38].

A complex approach for obtaining comprehensively substantiated kinetic models in heterogeneous catalysis is proposed. The kinetic models of catalytic conversions of different classes of organic compounds, established for the first time by this method, are described. Some theoretical premises and the consequences of this study are examined.

~~An introduction to kinetics in heterogeneous catalysis~~

In chemistry, heterogeneous catalysis is catalysis where the phase of catalysts differs from that of the reactants or products. Contrasts with homogeneous catalysis where the reactants, products and catalyst exist in the same phase. Phase distinguishes between not only solid, liquid, and gas components, but also

immiscible mixtures, or anywhere an interface is present. Catalysts are useful because they increase the rate of a reaction without themselves being consumed and are therefore reusable.

Catalysts allow a reaction to proceed via a pathway that has a lower activation energy than the uncatalyzed reaction. In heterogeneous catalysis, catalysts provide a surface to which reactants bind in a process of adsorption. In homogeneous catalysis, catalysts are in the same phase as the reactants.

The necessary first step in a heterogeneous catalytic reaction involves activation of a reactant molecule by adsorption onto a catalyst surface. The activation step implies that a fairly strong chemical bond is formed with the catalyst surface. This mode of adsorption is called chemisorption, and it is characterized by an enthalpy change typ

This distance dependency significantly influences the gross reaction kinetics and accounts for the observed nanoconfinement effects. We further found that a length scale below 25 nm is critical to avoid the limitation of short-lived species diffusion and achieve kinetics that are orders of magnitude faster than those obtained in a batch suspension of heterogeneous catalysts.

This textbook contains all the information needed for graduate students or industrial researchers to design kinetic experiments involving heterogeneous catalysts, to characterize these catalysts, to acquire valid rate data, to verify the absence of mass (and heat) transfer limitations, to propose reaction models, to derive rate expressions based on these models and, finally, to assess the consistency of these rate equations.

~~(PDF) Kinetics of heterogeneous catalytic reactions —~~

The conventional steady-state flow methods that are used widely to investigate the kinetics of heterogeneous catalytic reactions are limited, because under steady-state conditions, the elementary steps proceeding in series take place at the same rate, and the overall kinetics provides somewhat limited insight into the mechanism.
